Abstract

Twenty-four quinoxaline derivatives were evaluated for their antimycobacterial activity using BacTiter-Glo microbial cell viability assay. Five compounds showed MIC values < 3.1 μM and IC_{50} values < 1.5 μM in primary screening and therefore, they were moved on for further evaluation. Compounds **21** and **18** stand out, showing MIC values of 1.6 μM and IC_{50} values of 0.5 and 1.0 μM respectively. Both compounds were the most potent against three evaluated drug-resistant strains. Moreover, they exhibited intracellular activity in infected macrophages, considering log-reduction and cellular viability. In addition, compounds **16** and **21** were potent against non-replicating *M. Tb.* and compound **21** was bactericidal. Therefore, quinoxaline derivatives could be considered for making further advances in the future development of antimycobacterial agents.

Keywords: tuberculosis, antimycobacterial, quinoxaline, intracellular activity.

Abbreviations: TB, tuberculosis; *M. Tb.*, *Mycobacterium tuberculosis*; BTG, BacTiter-Glo microbial cell viability assay; MDG, Millennium Development Goals ; BFX, benzofuroxan; NRP, non-replicating; MBC, Minimal bactericidal concentration; LORA, Low Oxygen Recovery Assay; SDR, single drug-resistant; FBS, bovine serum; NA, Not available; RIF, Rifampicin; INH, Isoniazid; OFX, Ofloxacin.

Tuberculosis (TB) is a chronic infection caused by *Mycobacterium tuberculosis* (*M. Tb.*), which is the second cause of death from a single infectious agent. Due to its high infectivity it is estimated that a third of the world population is a reservoir of *Mycobacterium*.

In 2000, within the Millennium Development Goals (MDG6), the United Nations proposed to halt the spread and reverse the incidence of TB by 2015. Some of these objectives have already been achieved. The TB mortality rate has decreased 45% since 1990 and more people have access to effective treatments and to early and sensitive diagnostic methods. However, epidemiological data are still alarming¹. According to World Health Organization (WHO) data, 9 million people were infected by tuberculosis bacillus in 2013, including 1.1 million cases among people living with HIV. In 2013, 1.5 million people died due to tuberculosis infection, with this being the main cause of death among people affected by HIV. In addition, the number of infected people with multidrug-resistant TB (MDR-TB) is increasing annually. The ability of *M. Tb.* to develop resistance to drugs and the difficulties faced in the treatment of the TB-disease has facilitated the development of resistant strains. MDR-TB has been spreading rapidly in the last decades, especially in recent years; the number of individuals infected with MDR-TB tripled between 2009 and 2013, and reached 136,000 worldwide².

These data indicate the urgent need to continue working in the development of new compounds against new targets and with new mechanisms of action for treating MDR-TB. It is also important to shorten the long periods of treatment because they are a common reason for treatment discontinuation on the part of the patient, and stopping the treatment too early is related with the appearance of resistant strains³. With this aim, our group has been working for several years on the synthesis and biological evaluation of new structures derived from quinoxalines. Quinoxaline derivatives show very interesting biological properties. Several studies have been published which justify the interest in these derivatives as antibacterial agents. As a result of our anti-tuberculosis research project, several papers have been published in which both synthesis and biological activity assessments have been described for a large number of quinoxaline and quinoxaline 1,4-di-*N*-oxide derivatives with a variety of substituents. Some of them have shown growth inhibition values of 99% and 100%⁴⁻⁹. This indicates that these types of structures are very interesting for developing new anti-TB molecules. Furthermore, it has been reported that oxidation of the nitrogen in

the quinoxaline ring provides a significant increase in the antibacterial biological activity.¹⁰ It has also been reported that the quinoxaline 1,4-di-*N*-oxide derivatives suffer a bioreduction process under hypoxic conditions¹¹. This behavior could be interesting because in the caseous core of the tuberculous granulomas there is a low concentration of oxygen where non-replicating persistence (NRP) forms of *M. Tb.* bacilli can survive¹². These forms are thought to be the reason behind the need for long treatments and the development of tolerance to the treatment¹³.

Chalcones are precursors of flavonoids and isoflavonoids, which consist in two aromatic rings linked by a 3 carbons chain presenting an α,β -unsaturated ketone system. Chalcones exhibit a wide range of biological activities such as anticancer, anti-leishmaniasis, anti-inflammatory, anti-oxidant and anti-tuberculosis. With regard to the anti-mycobacterial activity of chalcones, there are numerous publications that justify their use in the search for new anti-TB compounds^{14, 15}.

Fluoroquinolones are an important group of broad spectrum antibiotics and they are present in many molecules with high antituberculosis activity such as gatifloxacin and moxifloxacin, which are under development in clinical trials¹⁶.

With the aim of developing new antitubercular drug candidates, we have synthesized and evaluated 24 quinoxaline derivatives. The design was based on the molecular hybridization of the quinoxaline 1,4-di-*N*-oxide with chalcone and fluoroquinolones scaffolds¹⁷. (**Figure 1**)

We report the design and synthesis of the quinoxaline 1,4-di-*N*-oxide derivatives **1-24**. The biological evaluation of the compounds included a *M. Tb.* H₃₇Rv dose-response assay (primary screening) in which the IC₅₀, IC₉₀ and MIC against *M. Tb.* were determined. The most active compounds were moved on to a more advanced testing stage for antimycobacterial activity. These assays included the evaluation against single drug-resistant (SDR) strains of *M. Tb.*, Minimum bactericidal concentration (MBC), Low Oxygen Recovery Assay (LORA) and intracellular drug activity. All results are reported and structure-activity relationships (SARs) are discussed.

The quinoxaline 1,4-di-*N*-oxide derivatives were synthesized through the synthetic process illustrated in **Scheme 1**.

Scheme 1: General synthesis of quinoxaline 1,4-di-*N*-oxide derivatives.

Reagents and conditions: (i) *N,N*-DMF, NaOCl, low temperature; (ii) ethanolamine, CaCl₂; (iii) microwave assisted synthesis; (iv) NaOH, MeOH, ice bath; (v) NaOH, MeOH, freezing bath; (vi) *N,N*-DMF, reflux; (vii) CH₃CN, Et₃N, rt.; (viii) CH₃CN, DBU, 50°C.

The starting benzofuroxans, were commercially available or were obtained by previously described methods¹⁸. The synthesis of quinoxaline 1,4-di-*N*-oxide intermediates were carried out by a variation of the Beirut reaction following the procedure described in the literature¹⁹⁻²¹.

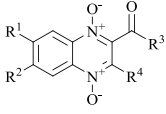

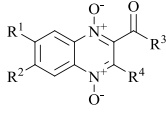

The 10 novel chalcone analogs (**1-10**) were prepared by Claisen-Schmidt condensation²². Benzaldehyde, 5-nitro-2-furaldehyde and 5-nitro-2-thiophenecarboxylaldehyde were used as the starting aldehyde. The corresponding quinoxaline 1,4-di-*N*-oxide previously synthesized was used as the ketone. The new derivatives **1-10** were unsubstituted or substituted in R¹ or R² positions by methyl moiety as electron-releasing groups and by chlorine moiety as electron-withdrawing groups.

The methodologies for the synthesis of compounds **11-15**, **17-20** and **22-24** were previously described by our group¹⁹. Compound **16** and **21** were obtained by nucleophilic aromatic substitution of chlorine or fluorine linked to R¹/R² substituent on the quinoxaline ring. Morpholine and 1-(4-fluorophenyl)piperazine were used as the nucleophilic amine. Compound **16** was obtained by reflux using *N,N*-DMF and compound **21** was obtained using DBU as base.

The identification of novel interesting compounds begins with a primary screening. This initial dose response assay evaluates the ability of compounds to inhibit the *M. Tb.* replication. The IC₉₀, IC₅₀ and MIC of the 24 quinoxaline 1,4-di-*N*-oxide derivatives were determined against *M. Tb.* H₃₇Rv (ATCC 27294) using BacTiter-Glo (BTG) microbial cell viability assay.

The structure and anti-tuberculosis activity data of the 24 compounds are shown in **Table 1**. Nine out of twenty-four evaluated compounds exhibited MIC values ≤ 6.2 μM and IC_{50} values < 3.7 μM . Compounds **3**, **16**, **18**, **21** and **24** were the most active, showing MIC values among 1.6-3.1 μM and IC_{50} values among 0.5-1.5 μM . These MIC and IC_{50} values were lower than those of the second-line reference drugs cycloserine and pyrimethamine, and also by the first-line drug ethambutol. It is worth noting that 4 out of the 5 most active compounds (**16**, **18**, **21** and **24**) are fluoroquinolone analogs while compound **3** belongs to chalcone analogs.

a: quinoxaline-1-*N*-oxide

In comparison with fluoroquinolones, the presence of an electron-withdrawing substituent (fluorine or chlorine) in only one of the R¹ and R² positions in the quinoxaline ring is important for biological activity. This behavior is observed

comparing the biological results obtained for compound **3** vs **1** and **2**, **6** vs **5**, **9** vs **7**, **8** and **10**, **13** vs **14**, **18** vs **19** and **24** vs **23**.

With respect to R⁴ substitutions, 8 out of 9 most active compounds present a trifluoromethyl group. The substitution of hydrogen by its bioisostere fluorine is a widely used strategy in the search for new compounds. The presence of fluorine atoms can change and radically modulate the physicochemical properties of organic compounds modifying its biological behavior²³. However, it is not possible to carry out a SAR study due to the limited structural variability in this position.

With regard to R³ position, it seems to be less important for the anti-mycobacterial activity.

With regard to *N*-oxide groups of the quinoxaline ring, these groups seem to be essential for the activity as we can see comparing compounds **15** vs **16**. This important loss of activity confirmed again that the presence of the both *N*-oxide groups is a structural requirement for biological activity^{24, 25}.

According to obtained results, compounds **3**, **16**, **18**, **21** and **24** (MIC < 6.25 μM) were submitted for advanced anti-mycobacterial susceptibility profiling. This advanced screening includes the determination of MIC against SDR strains of *M. Tb.*, MBC, LORA as well as intracellular drug screening study in infected macrophages and a MTT cell proliferation study in uninfected macrophages at different concentrations.

Table 2 shows the MIC values of the selected compounds against rifampin (RIF), isoniazid (INH) and ofloxacin (OFX) resistant strains and a retested MIC value against a susceptible strain.

Table 2. Minimum inhibitory concentration against single-drug resistant strains of *M. Tb.*

Code	Structure	H ₃₇ Rv		INH-R <i>M. Tb.</i>			RIF-R <i>M. Tb.</i>			OFX-R <i>M. Tb.</i>		
		SRI 1345 strain		SRI 1369 strain			SRI 1367 strain			SRI 4000 strain		
		MIC μg/mL	% Inh ^(a)	MIC μg/mL	% Inh.	R ^(b)	MIC μg/mL	% Inh.	R ^(b)	MIC μg/mL	% Inh.	R ^(b)
3		2	80	1	64	2	0.5	51	4	0.5	100	4
16		2	61	0.5	78	4	0.5	66	4	0.25	76	8
18		1	78	0.25	57	8	0.25	68	8	0.25	84	8
21		1.5	78	0.19	51	8	0.19	73	8	0.19	81	8

It is well known that quinoxaline 1,4-di-*N*-oxide possess a selective toxicity against hypoxic tumoral cells through a bioreductive activation process²⁸. In the case of tuberculosis, the granulomatous lesions formed in the infected lungs present a hypoxic environment where TB bacilli are in a latent state of low metabolic activity. These nonreplicating persistence (NRP) *M. Tb.* bacilli is thought to be a main factor responsible for the long treatment periods and the emergence of antimicrobial tolerance²⁹. Therefore, special attention should be paid to the NRP state of *M. Tb.* from the early stages of the drug discovery process. Therefore, the LORA assay, conducted under low oxygen conditions, has been included in the biological evaluation with the aim of identifying compounds able to acting on the non-replicative bacilli. As shown in **Table 3**, compounds **16** and **21** were more potent against NPR *M. Tb.* being 8-fold and 4-fold more active under anaerobic conditions than aerobic conditions respectively. These results offer an important approach for studying this family of compounds in these conditions due to the important role that NRP *M. Tb.* bacilli play in influencing the duration of treatment.

M. Tb. can evade the immune response of macrophages and has the ability to reside inside them in a latent state. This evasion mechanism makes the effectiveness of treatment difficult and increases the microbial resistance^{30, 31}.

With the aim of assessing the intracellular effectiveness of the 5 selected compounds in this infection phase, the activity in J774 infected macrophages was evaluated. Compounds **3**, **16**, **18**, **21** and **24** were tested at three 10-fold concentrations based on their MIC values against *M. Tb.* H₃₇Rv.

All of the evaluated compounds showed high log-reduction in the burden of the intracellular bacilli (**Table 4**). However, it was observed that none of the evaluated compounds showed dose response log-reduction in contrast to RIF.

At the lowest concentration, compounds **3** and **24** showed values > 2-log-reduction (> 99% inhibition) while compounds **16**, **18** and **21** showed values > 1-log-reduction (> 90% inhibition). Therefore, the 5 evaluated compounds exhibited log-reduction among 3 to 4.5-fold more than RIF.

Compounds **16**, **18** and **21** showed the highest log-reduction at the highest concentration and presented values of 26%, 65% and 47% of cellular viability respectively at this concentration. Therefore, compounds **18** and **21** stand out as being the most potent derivatives against intracellular bacilli, considering log-reduction and cell viability values.

Table 4. Intracellular activity in *M. tb* infected J774 macrophages.

Code	Log reduction ^a			% of cellular viability		
	Low conc ^b	Mid conc ^b	High conc ^b	Low conc ^b	Mid conc ^b	High conc ^b
3	2.11	1.68	1.76	70	81	26
16	1.68	1.57	2.67	88	37	37
18	1.74	1.5	2.66	83	53	65
21	1.43	1.41	3.86	60	64	47
24	2.17	1.66	1.76	70	81	26
RIF	0.48	1.73	2.68	93	87	80

^a Intracellular drug activity is reported as log reduction values calculated as reduction in *Mtb* concentration from zero hour to 7 days post-infection.

^b The three concentrations chosen were based on the MIC data generated in the HTS primary screen. The mid concentration bracketed the reported MIC with the lower concentration ten-fold below the mid and the higher concentration ten-fold above the mid.

In conclusion, we describe the synthesis of 12 new compounds and the antimycobacterial evaluation of 24 quinoxaline di-*N*-oxide derivatives. Five of the tested compounds passed the first cut-off established in the primary screening against H₃₇Rv, thereby justifying the great interest in this family of compounds. The results obtained in the advanced screening (MIC against H₃₇Rv and SDR-strains, MBC, LORA, intracellular activity and MTT cell proliferation) confirm the promising pharmacological profile of these derivatives.

Compounds **3**, **16**, **18**, **21** and **24** were active against INH, RIF and OXF-resistant strains suggesting that they could act through a different mechanism of action than the reference drugs. Moreover, the MIC and LORA assay show that compound **21** is potent not only against replicating *M. Tb* but also against NRP *M. Tb*. In addition, compound **21** could be classified as bactericidal according to the MBC and has also stand out in the intracellular drug activity assay. The mechanism of action of these compounds has not yet been studied.
